

Welcome to Riparian Book Club

Coalitions & Collaboratives (COCO) & Colorado Riparian Association (CRA) are teaming up with special co-host **Water Education Colorado (WEco)** to “book club” the:

Process-Based Restoration (PBR) Umbrella

We will explore on-the-ground projects from opposite ends of the PBR spectrum and why different approaches are appropriate in different scenarios

Riparian Book Club helps bridge the gap between academic research on stream and wetland systems and applied restoration design in Colorado

The Process-Based Restoration Umbrella—It isn't just about beavers

There's a lot of talk about the benefits of beavers in stream restoration, but Colorado's riparian systems are complex—when it comes to restoring stream systems, there isn't one tool that works in all situations. Rather, there are many tools in the restoration toolbox.

Process-based restoration (PBR) is an important category of restoration work that targets the root causes of ecosystem change and aims to restore a river's natural processes so the area can begin to self heal. But under the PBR umbrella, there is a spectrum of restoration approaches, which

includes active and passive recovery (beaver mimicry is considered active). Even with this diversity of approaches, certain characteristics define what fits within the PBR "umbrella."

Limitations:	Common level of design and analysis:
<ul style="list-style-type: none"> Not helpful when causative stressor (cause of degradation) cannot be removed (e.g., a dam or diversion structure) Not helpful for non-wadeable, higher order systems When causative stressor is other than loss of wood and beaver dams If beaver can't be expected to move in to the restored area, beaver mimicry structures may be built 	<ul style="list-style-type: none"> No design required for system Design for safe removal of the structure may be required Engineering design analysis not required LTPBR Manual 2019 provides "guidelines for implementing a subset of low-tech tools (i.e., B and PALs in riverscapes lacking wood and beaver dams"
<ul style="list-style-type: none"> Typically low risk areas with low or no infrastructure adjacency to accommodate floods covering full width of the valley bottom Access to full floodplain may currently be impractical due to anthropogenic constraints (Stage 5 or 6) Typically used in smaller watersheds with extensive floodplains 	<ul style="list-style-type: none"> Engineering design analysis varies, typically falling between LTPBR and HTPBR Analysis required to determine target slopes at minimum Full valley reset approach requires significant engineering design analysis
<ul style="list-style-type: none"> Applies to most systems and causative stressors because historical detailed analysis addresses site-specific conditions 	<ul style="list-style-type: none"> Heavier engineering design analysis required compared to other approaches, but varies greatly by project

Welcome | Riparian Book Club Hosts

Julie Ash, PE | Education & Outreach Committee Lead | Colorado Riparian Association (CRA)

To promote the conservation, restoration, and preservation of Colorado's riparian areas and wetlands.

CONSIDERATIONS WHEN SELECTING RESTORATION APPROACHES AND TREATMENTS

When selecting a restoration approach and treatment, water managers and restoration practitioners weigh the following factors. Passive recovery and low-tech active recovery projects fall toward the left and middle of these spectrums, while high-tech active recovery work is on the right side.

The Process-Based Restoration Umbrella—it isn't just about beavers

There's a lot of talk about the benefits of beavers in stream restoration, but Colorado's riparian systems are complex—when it comes to restoring stream systems, there isn't one tool that works in all situations. Rather, there are many tools in the restoration toolbox.

Process-based restoration (PBR) is an important category of restoration work that targets the root causes of ecosystem change and aims to restore a river's natural processes so the area can begin to self heal. But under the PBR umbrella, there is a spectrum of restoration approaches, which

includes active and passive recovery (beaver mimicry is considered active). Even with this diversity of approaches, certain characteristics define what fits within the PBR "umbrella."

Limitations:

- Not helpful when causative stressor (cause of degradation) cannot be removed (e.g., a dam or diversion structure)
- Not helpful for non-wadeable, higher order systems where causative stressor is other than loss of wood and beaver dams
- If beaver can't be expected to move in to the restored area, beaver mimicry structures may be built
- Typically low risk areas with low or no infrastructure adjacency to accommodate floods covering full width of the valley bottom
- Access to full floodplain may currently be impractical due to anthropogenic constraints—Stage Eight might work well instead with restoration to an extent rather than the full floodplain width

Common level of design and analysis required:

- No design required for system
- Design for safe removal of the structure may be required
- Engineering design analysis not required
- LTPBR Manual 2019 provides "guidelines for implementing a subset of low-tech tools (i.e., BE and PALs in riverscapes lacking wood and beaver dams"
- Engineering design analysis varies, typically falling between LTPBR and HTPBR
- Analysis required to determine target slopes at minimum
- Full valley reset approach requires significant analysis
- Heavier engineering design analysis required compared to other approaches, but varies greatly across-specific projects

The Process-Based Restoration Umbrella—it isn't just about beavers

I'm a lot of talk about the benefits of beavers in riparian restoration, but Colorado's riparian systems are complex—when it comes to restoring stream systems, there isn't one tool that works in all situations. Rather, there are many tools in the restoration toolbox.

Process-based restoration (PBR) is an important category of restoration work that targets the root causes of ecosystem change and aims to restore a river's natural processes so the area can begin to self heal. But under the PBR umbrella, there is a spectrum of restoration approaches, which

includes active and passive recovery (beaver mimicry is considered active). Even with this diversity of approaches, certain characteristics define what fits within the PBR "umbrella."

- Limitations:**
- Not helpful when causative stressor (cause of degradation) cannot be removed (e.g., a dam or diversion structure)
 - Not helpful for non-wadeable, higher order systems when causative stressor is other than loss of wood and beaver dams
 - If beaver can't be expected to move in to the restored area, beaver mimicry structures may be built
 - Typically low risk areas with low or no infrastructure adjacency to accommodate floods covering full width of the valley bottom
 - Access to full floodplain may currently be impractical due to anthropogenic constraints—Stage Eight might work well instead with restoration to an extent rather than the full floodplain width
 - Applies to most systems and causative stressors because customized detailed analysis addresses site-specific constraints
 - Higher cost of analysis and often construction as well
- Common level of design and analysis required:**
- No design required for system
 - Design for safe removal of the structure may be required
 - Engineering design analysis not required
 - LTPBR Manual 2019 provides "guidelines for implementing a subset of low-tech tools (i.e., BJs and PALs in riverscapes lacking wood and beaver dams"
 - Engineering design analysis varies, typically falling between LTPBR and HTPBR
 - Analysis required to determine target slopes at minimum
 - Full valley reset approach requires significant analysis
 - Heavier engineering design analysis required compared to other approaches, but varies greatly across-specific projects

CONSIDERATIONS WHEN SELECTING RESTORATION APPROACH AND TREATMENTS

When selecting a restoration approach and treatment, water managers and practitioners consider the following factors. Passive recovery and low-tech active recovery projects fall toward the left and middle of the spectrum, while high-tech active recovery work is on the right side.

LOWER RISK FACTORS: Risk factors include stream channel infrastructure, public safety, etc.

UNCERTAINTY ACCEPTABLE FOR PROJECT: Project tolerance or "appetite" for uncertainty; often but not always inversely proportional to risk.

LONGER TIME TO DESIRED GOALS ACCEPTABLE FOR PROJECT: Passive and low-tech approaches sometimes, but not always, require more time to see results.

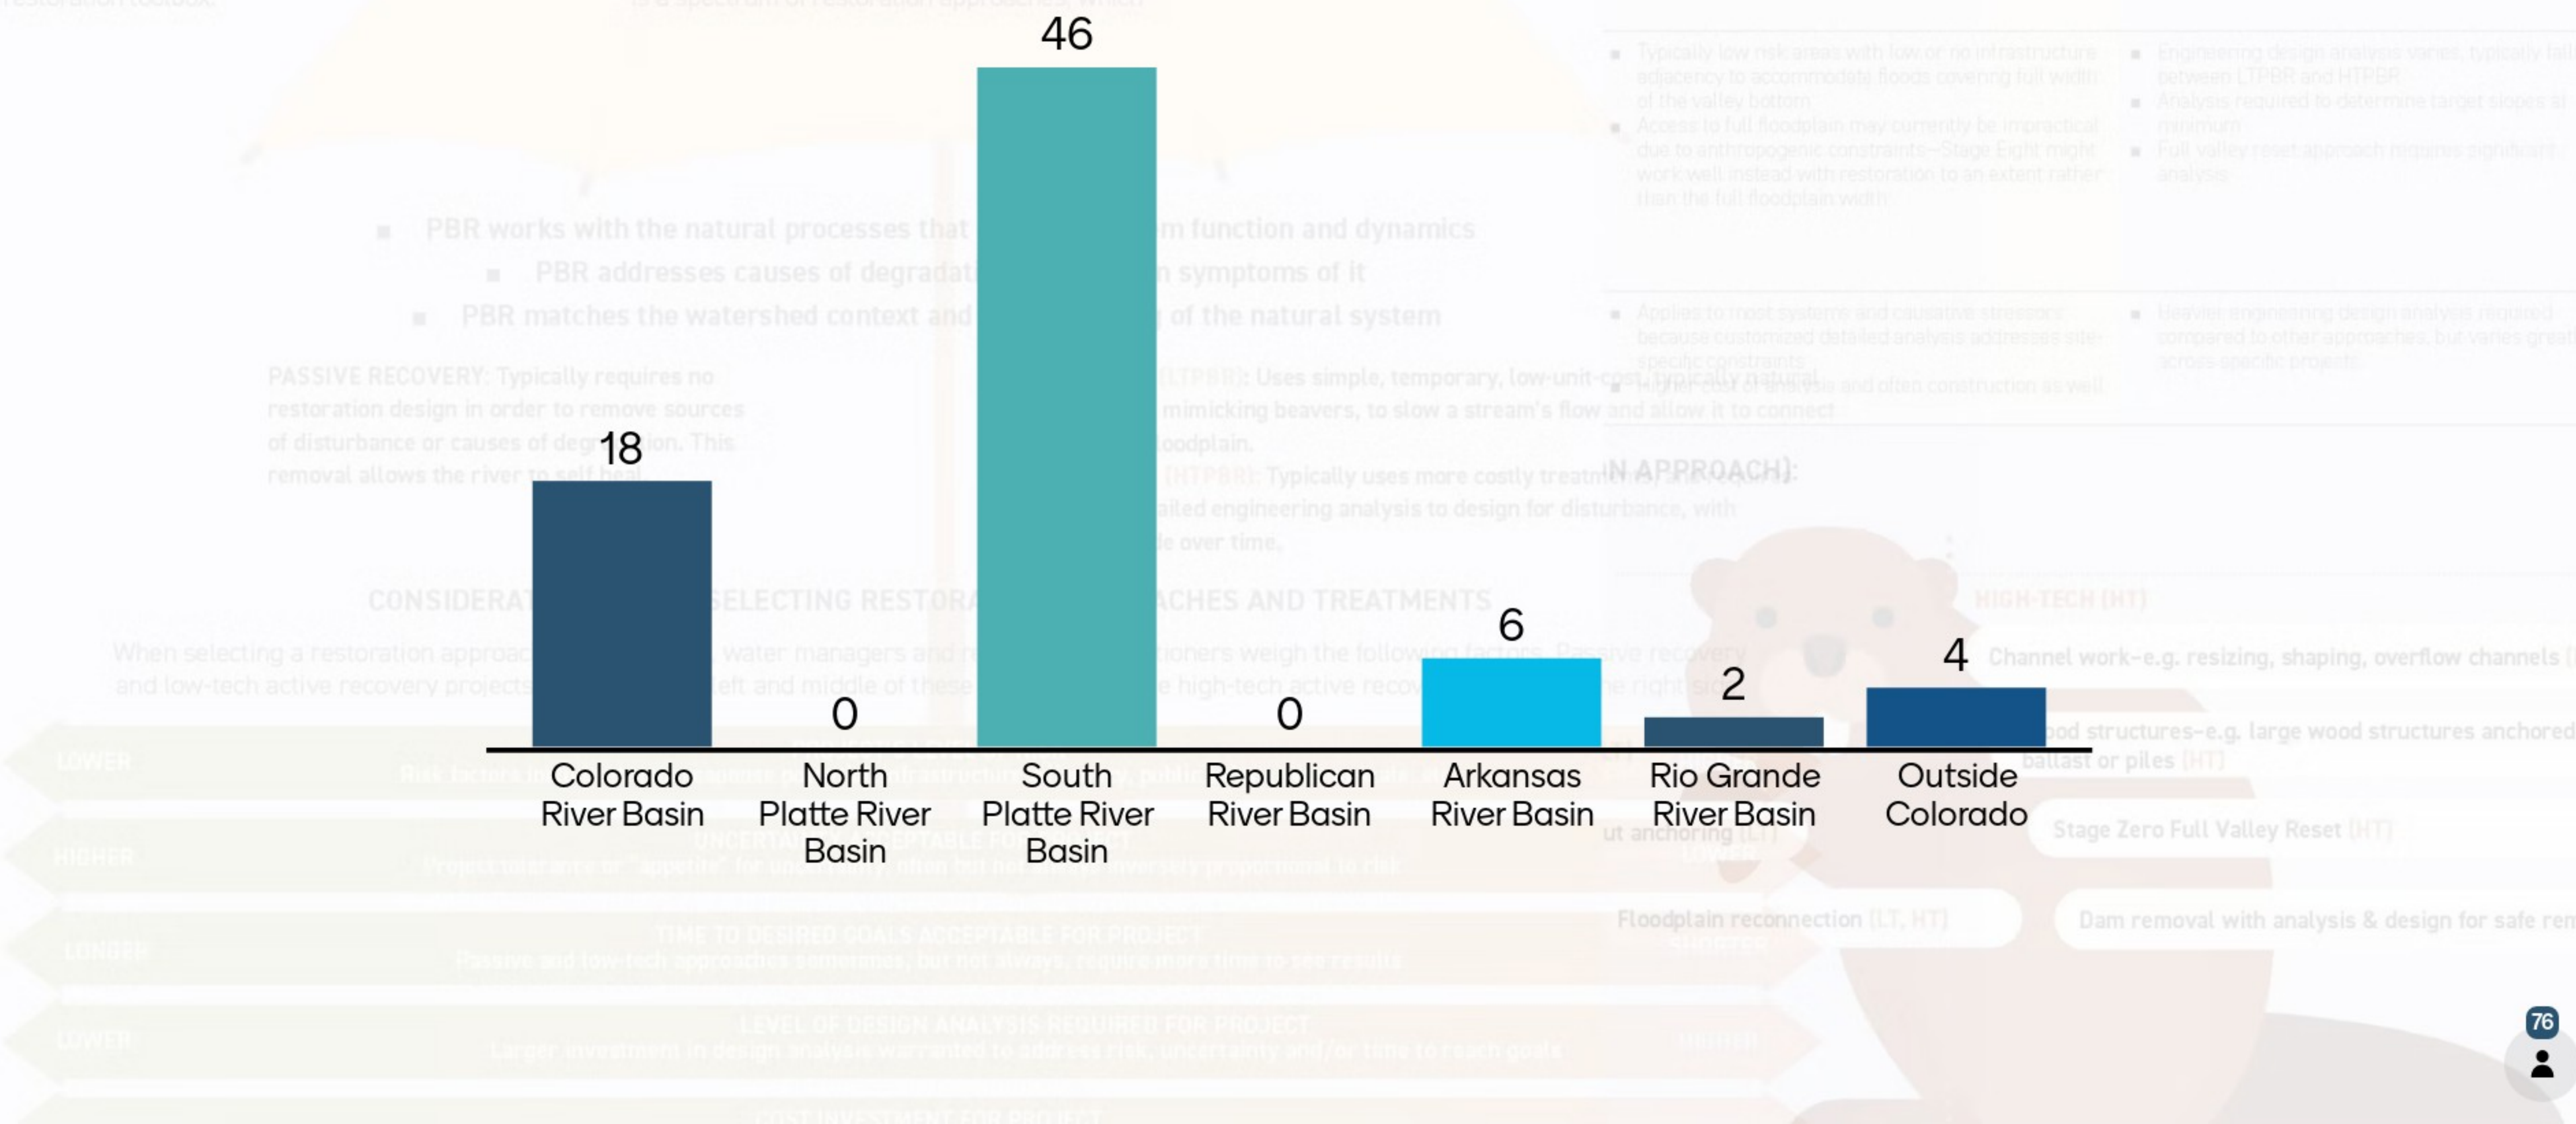

LOWER LEVEL OF DESIGN ANALYSIS REQUIRED FOR PROJECT: Larger investment in design analysis warranted to address risk, uncertainty and/or time to reach goals.

LOWER COST INVESTMENT FOR PROJECT:

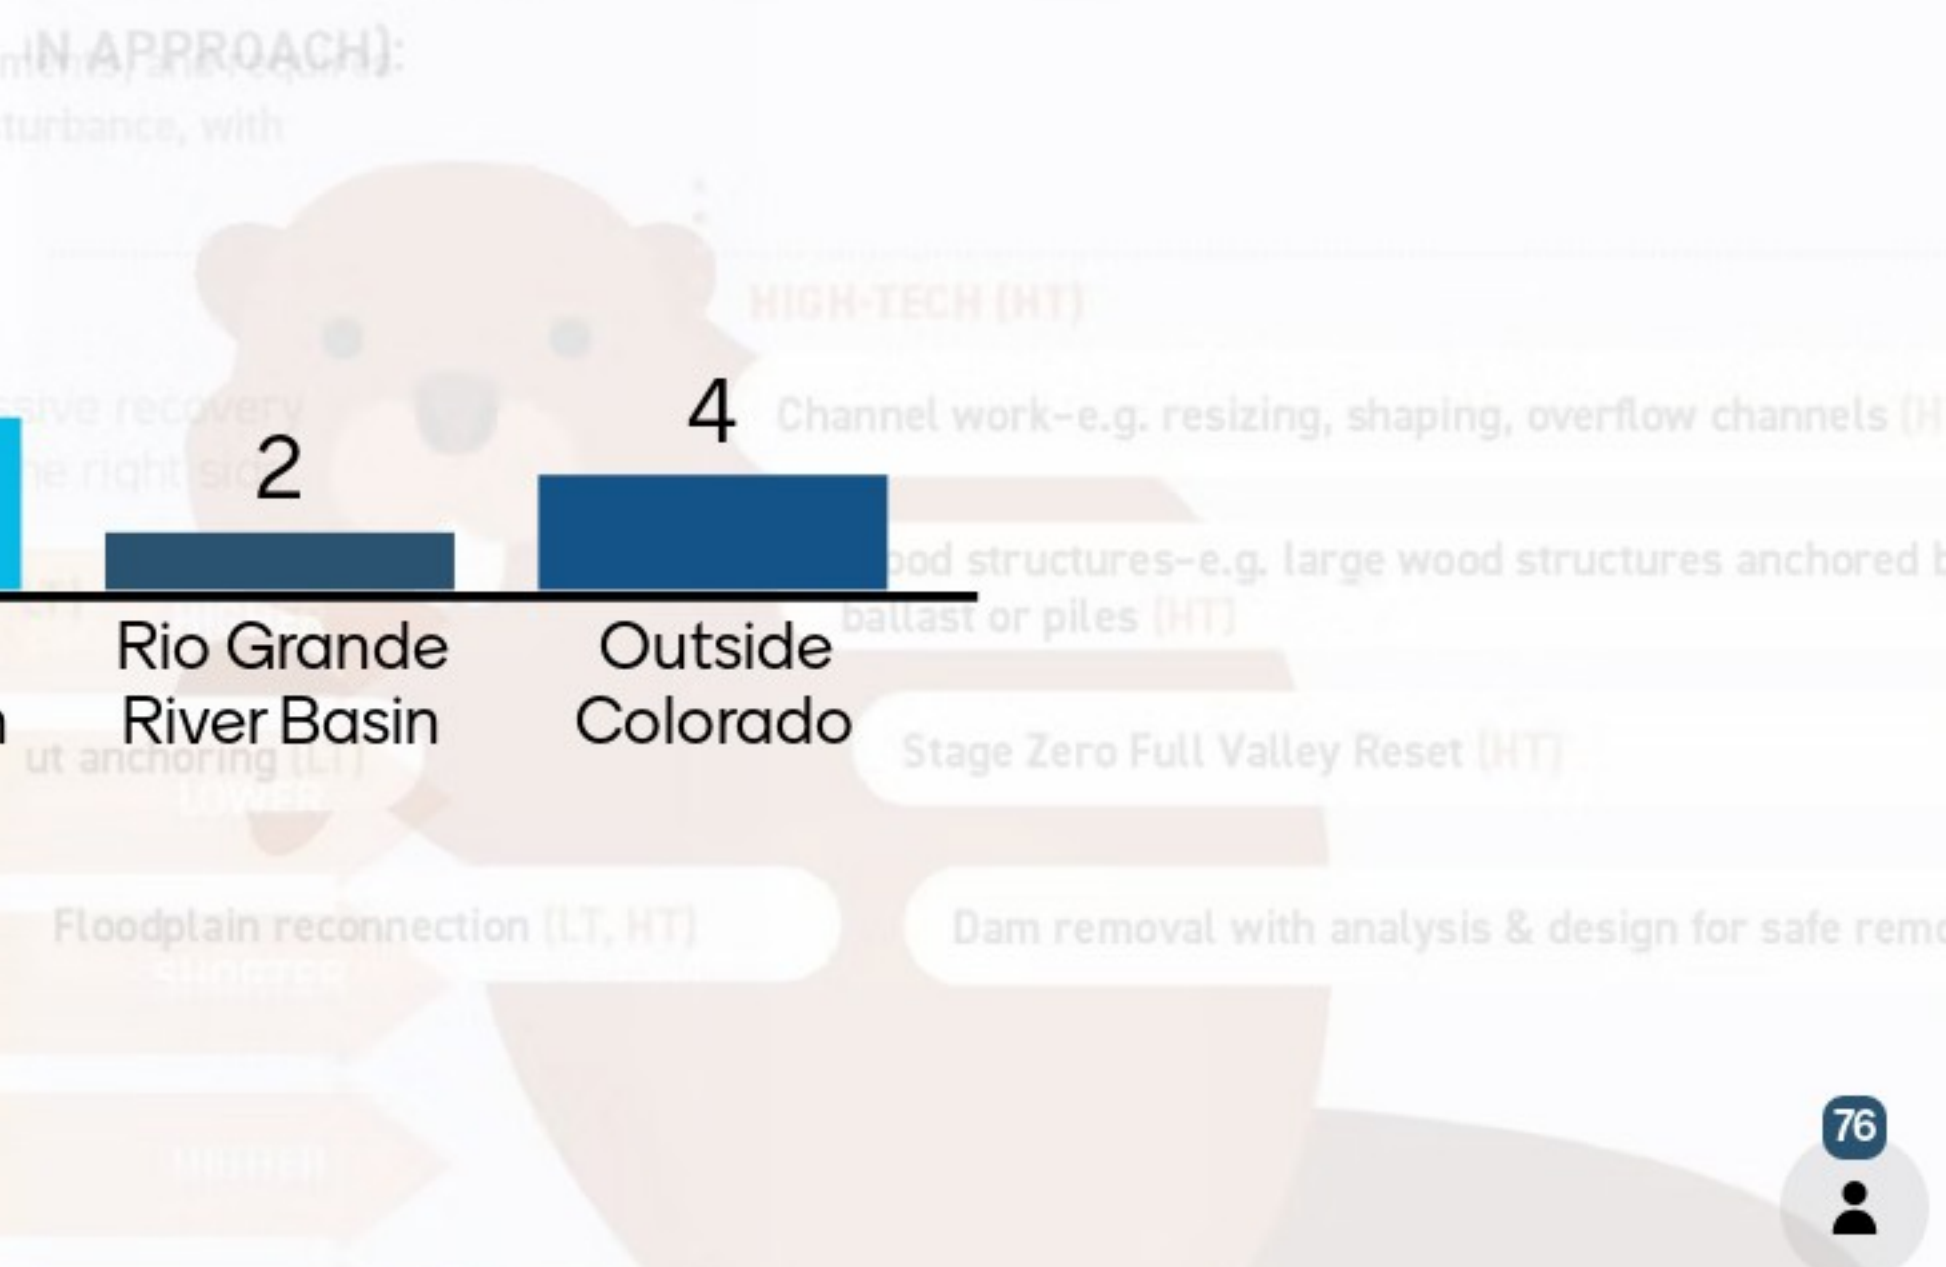

RESTORATION APPROACHES:

- Channel work—e.g. resizing, shaping, overflow channels (HT)
- Wood structures—e.g. large wood structures anchored by ballast or piles (HT)
- Stage Zero Full Valley Reset (HT)
- Dam removal with analysis & design for safe removal (HT)
- But anchoring (LT)
- Floodplain reconnection (LT, HT)

What geographic location are you joining us from?

- Limitations:**
- Not helpful when causative stressor (cause of degradation) cannot be removed (e.g., a dam or diversion structure)
 - If beaver can't be expected to move in to the restored area, beaver mimicry structures may be built
 - Typically low risk areas with low or no infrastructure adjacency to accommodate floods covering full width of the valley bottom
 - Access to full floodplain may currently be impractical due to anthropogenic constraints—Stage Eight might work well instead with restoration to an extent rather than the full floodplain width
 - Applies to most systems and causative stressors because customized detailed analysis addresses site-specific constraints
- Common level of design and analysis:**
- No design required for system
 - Design for safe removal of the dam
 - Engineering design analysis not required
 - Engineering design analysis varies, typically falling between LTPBR and HTPBR
 - Analysis required to determine target slopes at minimum
 - Full valley reset approach requires significant analysis
 - Heavier engineering design analysis required compared to other approaches, but varies greatly across specific projects

September 12, 2023 Riparian Book Club:

Process-Based Restoration (PBR) Umbrella

Building from the 1st Book Club on pivotal scientific papers on PBR, we will “book club” the PBR Umbrella graphic included in the Summer 2023 issue of WEco’s Headwaters publication

The Process-Based Restoration Umbrella—It isn't just about beavers

There's a lot of talk about the benefits of beavers in stream restoration, but Colorado's riparian systems are complex—when it comes to restoring stream systems, there isn't one tool that works in all situations. Rather, there are many tools in the restoration toolbox.

Process-based restoration (PBR) is an important category of restoration work that targets the root causes of ecosystem change and aims to restore a river's natural processes so the area can begin to self heal. But under the PBR umbrella, there is a spectrum of restoration approaches, which includes active and passive recovery (beaver mimicry is considered active). Even with this diversity of approaches, certain characteristics define what fits within the PBR “umbrella.”

- PBR works with the natural processes that drive ecosystem function and dynamics
 - PBR addresses causes of degradation, rather than symptoms of it
 - PBR matches the watershed context and human setting of the natural system

PASSIVE RECOVERY: Typically requires no restoration design in order to remove sources of disturbance or causes of degradation. This removal allows the river to self heal.

LOW-TECH PBR (LTPBR): Uses simple, temporary, low-unit-cost, typically natural structures, often mimicking beavers, to slow a stream's flow and allow it to connect with its natural floodplain.

HIGH-TECH PBR (HTPBR): Typically uses more costly treatments, and requires planning and detailed engineering analysis to design for disturbance, with adjustments made over time.

CONSIDERATIONS WHEN SELECTING RESTORATION APPROACHES AND TREATMENTS

When selecting a restoration approach and treatment, water managers and restoration practitioners weigh the following factors. Passive recovery and low-tech active recovery projects fall toward the left and middle of these spectrums, while high-tech active recovery work is on the right side.

LOWER	PROJECT'S LEVEL OF RISK Risk factors include stream response potential, infrastructure adjacency, public safety, system scale, etc.	HIGHER
HIGHER	UNCERTAINTY ACCEPTABLE FOR PROJECT Project tolerance or “appetite” for uncertainty, often but not always inversely proportional to risk.	LOWER
LONGER	TIME TO DESIRED GOALS ACCEPTABLE FOR PROJECT Passive and low-tech approaches sometimes, but not always, require more time to see results.	SHORTER
LOWER	LEVEL OF DESIGN ANALYSIS REQUIRED FOR PROJECT Larger investment in design analysis warranted to address risk, uncertainty and/or time to reach goals.	HIGHER
LOWER	COST INVESTMENT FOR PROJECT May apply to design, permitting, and/or construction costs; sometimes larger investments decrease time to get results.	HIGHER

DETAILS & APPLICABILITY FOR PBR APPROACHES:

Approach	Developed for or applicable to:	Limitations:	Common level of design analysis required:
Passive Recovery (P)	<ul style="list-style-type: none"> Any system 	<ul style="list-style-type: none"> Not helpful when causative stressor (cause of degradation) cannot be removed (e.g., a dam or diversion structure) 	<ul style="list-style-type: none"> No design required for system recovery Design for safe removal of the causative stressor may be required
LTPBR & other beaver mimicry (LT), including Beaver Dam Analogs (BDAs), Post-Assisted Log Structures (PALs), Simulated Beaver Structures (SBS)	<ul style="list-style-type: none"> Wadeable streams (aka low-order, often headwaters streams) Systems where degradation is caused by structural starvation of wood and beaver dams Targeted where beavers existed historically Typically requires adaptive management 	<ul style="list-style-type: none"> Not intended for non-wadeable, higher order systems where causative stressor is other than loss of wood and beaver dams If beaver can't be expected to move in to the restored area, beaver mimicry structures may be built 	<ul style="list-style-type: none"> Engineering design analysis not required LTPBR Manual 2019 provides “guidelines for implementing a subset of low-tech tools (i.e., BDAs and PALs) in riverscapes lacking wood and beaver dams”
Stage Zero Design (LT or HT) Stage Zero falls between LT & HT in required analysis and construction cost. Smaller Stage Zero efforts may have LT characteristics, but a larger project such as work covering a full valley, is closer to HT.	<ul style="list-style-type: none"> Most successful in depositional areas with wide valleys and mild slopes to promote deposition Often in small, incised streams in wet meadow headwaters, but can be up-scaled to larger rivers Promote processes that will nudge the system back toward a Stage Zero condition May need sediment supply from upstream to fill incised channels over time Works best with adaptive management, but not required 	<ul style="list-style-type: none"> Typically low risk areas with low or no infrastructure adjacency to accommodate floods covering full width of the valley bottom Access to full floodplain may currently be impractical due to anthropogenic constraints—Stage Eight might work well instead with restoration to an extent rather than the full floodplain width 	<ul style="list-style-type: none"> Engineering design analysis varied, typically falling between LTPBR and HTPBR Analysis required to determine target slopes at minimum Full valley reset approach requires significant analysis
HTPBR (HT)	<ul style="list-style-type: none"> Detailed analysis allows PBR application on a case-by-case basis to any system Works best with adaptive management 	<ul style="list-style-type: none"> Applies to most systems and causative stressors because customized detailed analysis addresses site-specific constraints Higher cost of analysis and often construction as well 	<ul style="list-style-type: none"> Heavier engineering design analysis required compared to other approaches, but varies greatly across specific projects

EXAMPLES OF TREATMENTS (NOTING OVERLAP ACROSS RESTORATION APPROACH):

PASSIVE RECOVERY (P)	ACTIVE RECOVERY	
	LOW-TECH (LT)	HIGH-TECH (HT)
Eliminate grazing (P)	Leaky beaver dam features (LT)	Channel work—e.g. resizing, shaping, overflow channels (HT)
Fence out grazing (P)	Wood structures—e.g., BDAs, PALs (LT)	Wood structures—e.g. large wood structures anchored by ballast or piles (HT)
Remove invasive weed species (P)	Wood placement without anchoring (LT)	Stage Zero Full Valley Reset (HT)
Gravel augmentation (P, LT)	Floodplain reconnection (LT, HT)	Dam removal with analysis & design for safe removal (HT)

Outside Colorado

If water rights weren't a concern, would you have included BDAs in your project design?

How are you measuring aggregation at the sites?

Have you made any predictive calculations on sediment capture? Or any plans to do so with monitoring?

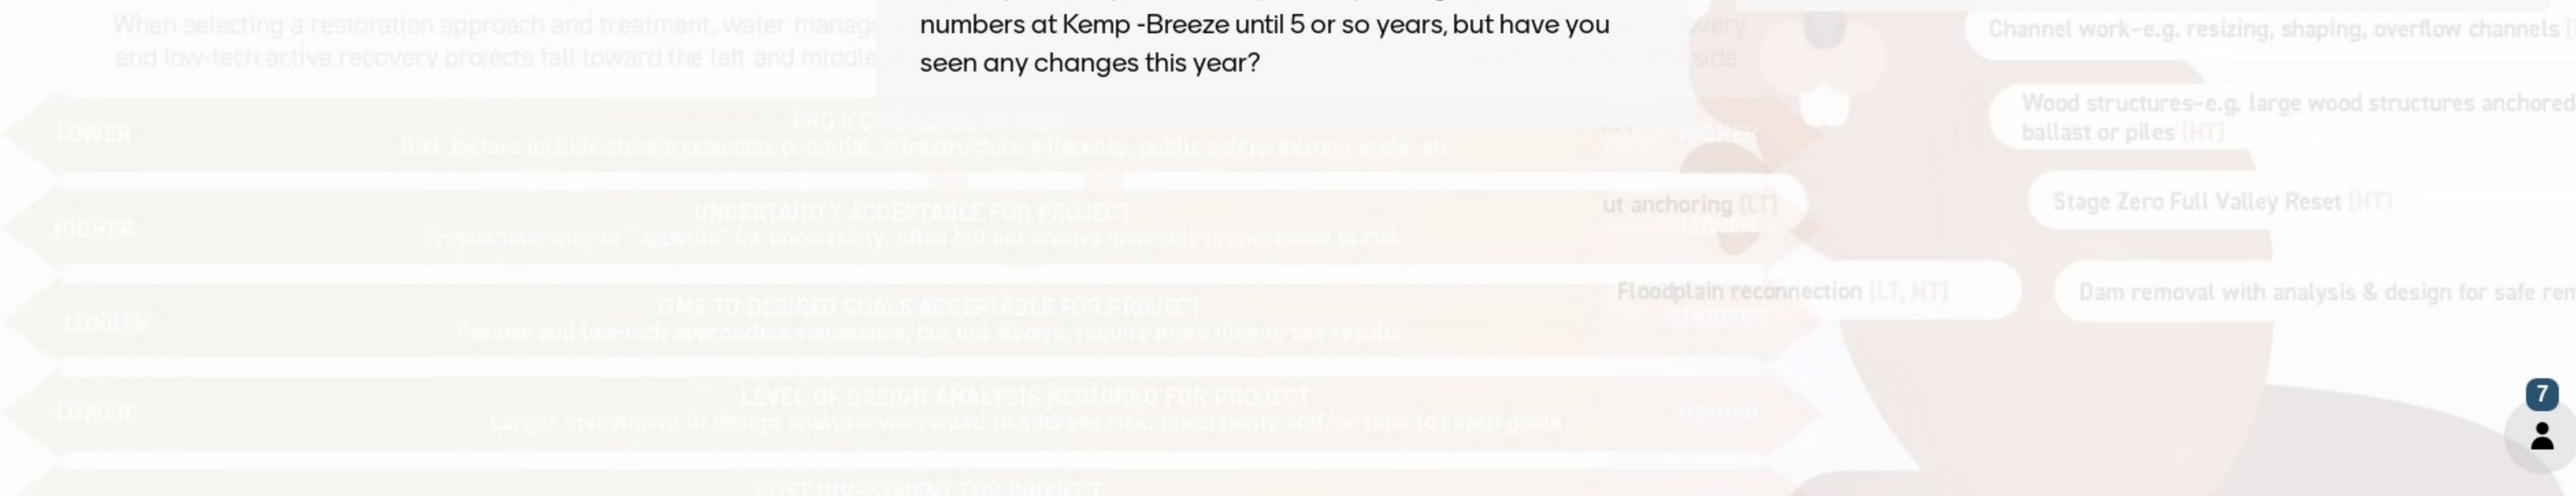

Are you seeing same increases in run-off across burn areas for snowmelt & rain? Comes from experience in recent years of run-off from snow melt being much lower in relation to snowpack. Correlation?

Has anyone studied the long term impacts of beaver structures in a watershed vs. watersheds without beaver structures? Does CWCB consider beaver structures to be consumptive or non-consumptive uses?

Where do you decide to place large Woody material? Can it be placed incorrectly causing more degradation

I know you said you didn't expect any change in fish/macro numbers at Kemp -Breeze until 5 or so years, but have you seen any changes this year?

How much did the first phase of construction cost?

Riparian Book Club Discussion 20 responses

In stream restoration, but Colorado's riparian stream systems, there isn't one tool that works in all situations. Rather, there are many tools in the restoration toolbox.

Process-based restoration (PBR) is an important category of restoration work that targets the root causes of ecosystem change and aims to restore a river's natural processes so the area can begin to self heal. But under the PBR umbrella, there is a spectrum of restoration approaches, which

includes active and passive recovery (beaver mimicry is considered active). Even with this diversity of approaches, certain characteristics define what fits within the PBR "umbrella."

Limitations:

- Not helpful when causative stressor (cause of degradation) cannot be removed (e.g., a dam or diversion structure)
- Not helpful for non-wadeable, higher order systems
- When causative stressor is other than loss of wood and beaver dams
- If beaver can't be expected to move in to the restored area, beaver mimicry structures may be built
- Typically low risk areas with low or no infrastructure

Common level of design and analysis required:

- No design required for system
- Design for safe removal of the structure may be required
- Engineering design analysis not required
- LTPBR Manual 2019 provides "guidelines for implementing a subset of low-tech tools (i.e., BDA and PALs) in riverscapes lacking wood and beaver dams"
- Engineering design analysis varies, typically falling

How long did it take to get the permits from ACOE and state to do the inchannel and connected physical system work?

Have you considered making permeable BDA structures?

Is Adaptive Management integrated into the project plans and if so does it have appropriate authorities and administrative support to implement?

Are you measuring changes in ground water levels?

Which factors primarily determine which structure is ideal?

What is the difference between the wood structures you use and those that imitate beaver dams?

For the low-tech project, who installed the structures? Volunteers, Forest Service crews, etc?

Current beaver work being done
<https://www.e3ecologic.org/restoring-beaver-habitat>

I recommend talking with Peter May in Crestone he is doing research on beavers and can offer some great insights

The Process-Based Restoration Umbrella—it isn't just about beavers

includes active and passive recovery (beaver mimicry is considered active). Even with this diversity of approaches, certain characteristics define what fits within the PBR "umbrella."

Limitations:	Common level of design and analysis:
<ul style="list-style-type: none"> Not helpful when causative stressor (cause of degradation) cannot be removed (e.g., a dam or diversion structure) Not helpful for non-wadeable, higher order systems When causative stressor is other than loss of wood and beaver dams If beaver can't be expected to move in to the restored area, beaver mimicry structures may be built 	<ul style="list-style-type: none"> No design required for system Design for safe removal of the structure may be required Engineering design analysis not required LTPBR Manual 2019 provides "guidelines for implementing a subset of low-tech tools (i.e., BJs and PALs in riverscapes lacking wood and beaver dams"
<ul style="list-style-type: none"> Typically low risk areas with low or no infrastructure adjacency to accommodate floods covering full width of the valley bottom Access to full floodplain may currently be impractical due to anthropogenic constraints—Stage Eight might work well instead with restoration to an extent rather than the full floodplain width 	<ul style="list-style-type: none"> Engineering design analysis varies, typically falling between LTPBR and HTPBR Analysis required to determine target slopes at minimum Full valley reset approach requires significant analysis
<ul style="list-style-type: none"> Applies to most systems and causative stressors because customized detailed analysis addresses site-specific conditions 	<ul style="list-style-type: none"> Heavier engineering design analysis required compared to other approaches, but varies greatly

- PBR works with the natural processes that drive ecosystem health and dynamics
 - PBR addresses causes of degradation, rather than symptoms of it
 - PBR matches the watershed context and human setting of the natural system

Thank You

A recording of this webinar will be available at <https://coloradoriparian.org/education-and-outreach-colorado-stream-restoration-network/> and <https://co-co.org/cra-csrn-riparian-book-club/> You will also receive a follow-up email of the recording with links to any resources shared.

Please stay tuned for future Riparian Book Clubs!
